Pattern 1: Sliding Window

Sliding Window is a powerful technique used in coding interviews to solve problems that involve finding a subsequence or a subarray in a given array or string. The technique involves maintaining a window of a fixed size or a variable size that slides over the array or string while keeping track of the relevant information within the window.

Fixed Sliding Window

In a fixed sliding window, the size of the window remains constant throughout the traversal of the array or string. The window moves from the beginning to the end, one element at a time, while maintaining the relevant information within the window.

Variable Sliding Window

In a variable sliding window, the size of the window changes dynamically based on the conditions or requirements of the problem. The window expands or contracts as it slides over the array or string, adjusting its size to capture the relevant information.

When to Use Sliding Window

Sliding Window is a useful technique when dealing with problems that involve finding a subsequence or a subarray in a given array or string. It is particularly useful when the problem requires keeping track of a contiguous subsequence or subarray that satisfies certain conditions or requirements.

Advantages of Sliding Window

- Efficiency: Sliding Window allows for efficient traversal of the array or string, as it only requires one pass through the data.
- Memory efficiency: The technique uses a fixed or variable amount of memory to store the relevant information within the window.
- Simplicity: The technique is relatively simple to implement and understand.

Disadvantages of Sliding Window

- Limited applicability: Sliding Window is not applicable to all problems, only those that involve finding a subsequence or a subarray that satisfies certain conditions or requirements.
- Complexity: The technique can be complex to implement in some cases, especially when dealing with variable sliding window.
